UNDERSTANDING DESIGN AUTOMATION

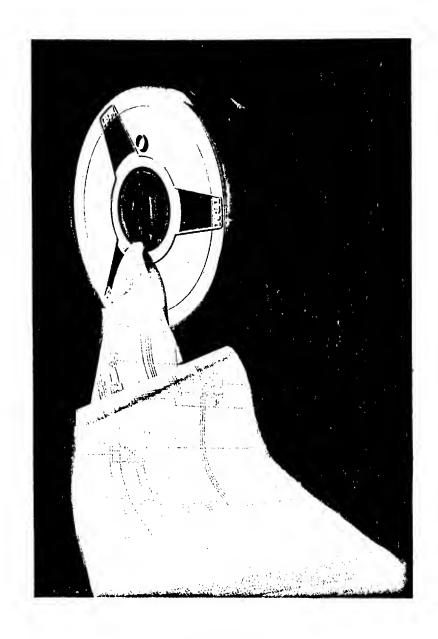

(Dept. 246 -- March 1, 1962)

IBM CONFIDENTIAL

This document contains information of a proprietary nature. ALL INFORMATION CONTAINED HEREIN SHALL BE KEPT IN CONFIDENCE. None of this information shall be divulged to persons other than: IBM employees authorized by the nature of their duties to receive such information or individuals or organizations authorized by the Data Systems Division in accordance with existing policy regarding release of company information.

Product Development Laboratory, Data Systems Division International Business Machines Corporation, Poughkeepsie, New York

FOREWORD

The purpose of this brochure is to assist the engineer in understanding the over-all Design Automation System. The simple portrayal of the computer system with respect to inter-relations between the stages of the system and with respect to input-output documents is shown. Equally important facts such as (1) the procedure for implementing Design Automation, (2) the documents required for releasing a machine, and (3) the planning of work-loads are stated. Becoming familiar with the following pages will lead to a better comprehension of how to effectively utilize Design Automation.

CONTENTS

CLOSING THE DEVELOPMENT TIME GAP
THE DESIGN AUTOMATION PROGRAM
Stage 1, Preparation of Master Tape, 4
Stage 2, System Page Validity Check, 6
Stage 3, Panel Wiring, 8
Illustrations of Output, Figures 1-15, 10-19
HOW TO IMPLEMENT DESIGN AUTOMATION
The Importance of Liaison, 20
Scheduling the Workload, 22
Understanding Work Flow, 22
To Release a Machine, 23

CLOSING THE DEVELOPMENT TIME GAP

Leadership in the computer field depends upon a company's ability to produce the most advanced data processing equipment. This in turn is dependent upon the utilization of advanced technologies as soon after their development as possible. The length of the time lag between the development of new circuitry and its incorporation in a new computer system, for example, can make the difference between success and failure.

Design automation is one means of closing the development time gap. It provides for the expeditious processing and updating of a machine by computer means. Computers are used for the preparation of manufacturing and customer engineering documents, the effective debugging on paper of a machine system, and the automatic routing of wire as well as the determining of wire-type on an SMS panel.

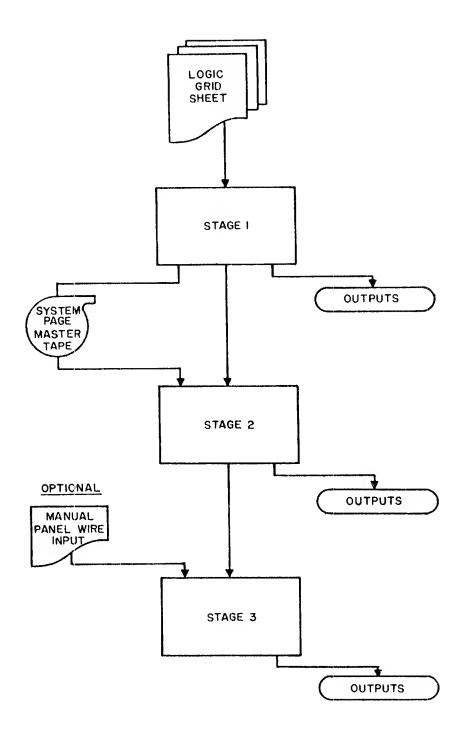

Another feature of design automation is the advantage of conformity of the logic representation. All machine systems are similar in respect to the layout of the system page. Customer engineering finds uniformity in system-page terminology helpful when educating men on two different machine systems.

Design automation is also a flexible and dynamic system. Program changes can be made to accommodate certain special requests. To obtain specific results, prespecifications that override certain computer decisions can be instituted. It is felt that the areas of machine simulation and fabrication offer the greatest promise for future progress in this program.

THE DESIGN AUTOMATION PROGRAM

There are three basic stages within the design automation program: Stage 1, Preparation of system page master tape; Stage 2, System page validity check; Stage 3, Panel wiring. Each stage is dependent on the output of a preceding stage, yet every one is run separately. Numerous computer programs make up the framework of each stage. The scope of these particular programs will not be discussed here.

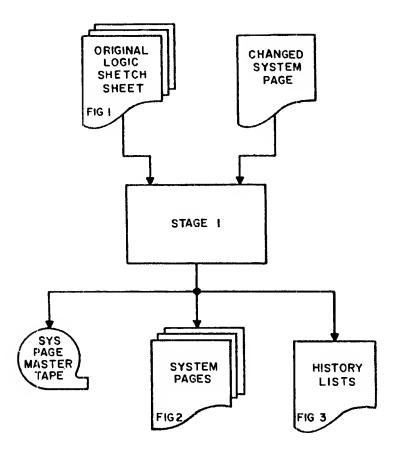

The outputs from the stages consist of documents which contribute to development of the final machine. The system page tape which is generated from Stage 1 is the master document from which subsequent stages operate, and to which all logical design changes or additions are applied. A manual panel wire input into Stage 3 is optional. Its purpose is to enable the processing of panel wiring in a uniform manner for special situations that require the first two stages to be by-passed. It is also used to enter service wiring, to enable engineering intervention, and to control unique situations while obtaining the bulk of the signal wiring automatically. A closer look at each of the three stages follows.

Three Stages of the General Program

Stage 1, Preparation of System Page Master Tape -- Original pages or changes to existing systems pages are keypunched into machine language, edited for accuracy, and merged in sequence by systems page number on the master tape. The master tape is the document from which system pages are printed and to which the checking programs are applied.

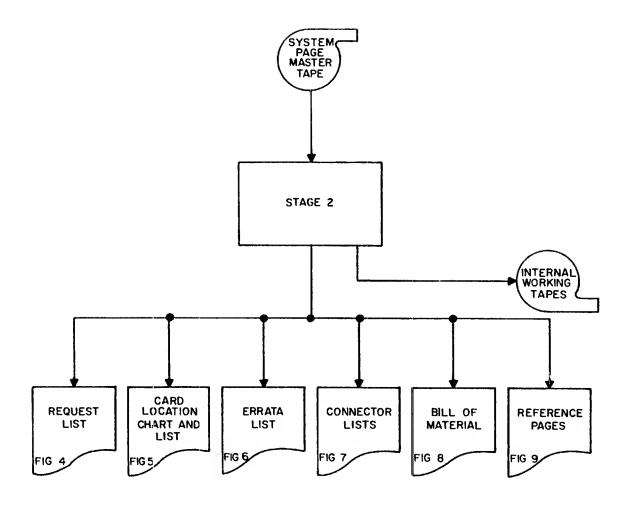

Blanket changes to systems pages on existing master tapes, such as changing machine designations, machine location on logic blocks, and system page numbering, can be accomplished by present computer programs. All released engineering levels for a released system page are retained on tape. System's printouts can be obtained for any page at any level.

Figures referred to here begin on page 10

Stage 1 - Preparation of System Page Master Tape

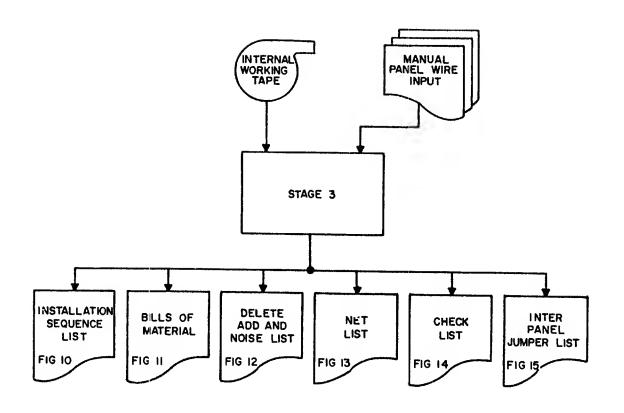

Stage 2. System Page Validity Check -- The machines systems are checked for electrical accuracy, interpage communication and package standardization. Errors are indicated, but not automatically corrected. The accumulation of data leads to direct outputs from Stage 2 as well as panel wiring outputs from Stage 3.

Figures referred to here begin on page 12

Stage 2 - System Page Validity Check

Stage 3, Panel Wiring -- Panel pin data accumulated from the systems pages or from manually produced data is automatically routed. Wire types are upgraded if the noise voltage pickup is detrimental to operation and downgraded if the length of the coaxial or twisted pair wire is impractical for installation. Add and delete instructions are produced when engineering changes are made to existing wired panels. Manual inputs to the program are only used when expedited panel wire changes are required.

Figures referred to here begin on page 17

Stage 3 - Panel Wiring

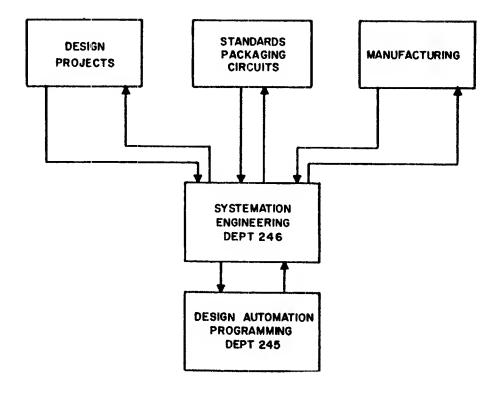

Figure 15 - Interpanel Jumper List Consists of Wires that Connect Directly from one Panel to another on the same Gate without Passing through the usual Edge Connectors.

HOW TO IMPLEMENT DESIGN AUTOMATION

Development groups using the facilities of design automation should be familiar with organizational procedures and computer programs. The effective use of this system will directly reflect in the records maintenance, the manpower requirements, and the scheduling of a machine from the concept to release. The following points are offered as a guide for the effective implementation of design automation.

- 1. Contact liaison group, Dept. 246, for the assignment of personnel for technical assistance.
- 2. Instruct all engineers and designers on the input requirements. (This service available from Dept. 246.)
 - a. Logic grid sheets
 - b. Checking program forms
 - c. Back panel wiring program forms
- 3. Request manuals and all written information about design automation.
- 4. Assign personnel to coordinate with design automation about all pertinent problems regarding the records.
- 5. Coordinate new circuit information to insure compatibility and installation in the design automation programs.
- 6. Resolve all packaging problems to insure compatibility with the present and future programs.
- 7. Inform Dept. 246 about schedules of workloads.
- 8. Contact Dept. 240 for assistance in budgeting the use of design automation.

The Importance of Liaison cannot be stressed too much. Initial contact with design automation should be made through Dept. 246, Systemation Engineering. Design automation, on the other hand, is concerned with general subjects in three areas: design, standards, and manufacturing. A breakdown of subjects according to area is as follows:

Liaison to Design Projects

- A. Education
- B. Procedure modifications
- C. Program modifications
- D. Circuit logical block descriptions

Liaison to Standards

- A. Circuit logical block description
- B. Program modifications due to package changes

Manufacturing

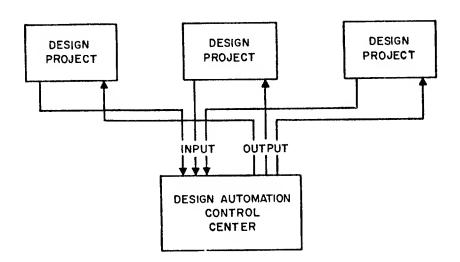

- A. Format of outputs
- B. Input criteria for automated assembly machines

Proper Scheduling of the Workload should be taken into consideration if bottlenecks are to be avoided. Managers of systems that comprise hundreds of system pages should be mindful of the delays that can arise if an excessive number of pages are submitted at one time. The initial transformation of the basic system page into machine language is the most time-consuming operation; therefore, pages should be submitted in groups of about thirty in chronological order of completion.

A second operation in which prior planning is important is the correcting of errors resulting from the checking programs. Large machines require three or four correction re-cycles before the system's pages are in order. Delays of one day or more during correcting periods eventually lead to three or four weeks before the systems are ready to extract panel wiring. This re-cycle time can be shortened by:

- 1. Forming teams of two or three men each to correct the errors.
- 2. Thoroughly examining each error code.
- 3. Have engineering assistance available when technical problems arise.
- 4. Accurately making corrections to the systems to eliminate any reoccurrence.

Understanding Work Flow can be an aid to those who maintain liaison with design automation. Representatives from design projects should submit all

production inputs to the control center, which is responsible for the scheduling of work through all of the stages of the program. Outputs, as well,

are controlled from the center, which also processes inquiries regarding the status of any job.

Facilities available at the computational laboratory, in addition to the control center, include:

System Page Control Section where the production inputs to Stage 1 are set up.

Keypunch Section where logic sketch sheets and changed system pages are keypunched into machine language.

System Page Edit Section where output pages are edited for accuracy.

Checking Control Section where the production inputs to Stage 2 are set up.

Panel Wire Control Section where the production inputs to Stage 3 are set up.

700 Series Computer Section where two 705 computers and one 704 computer are employed.

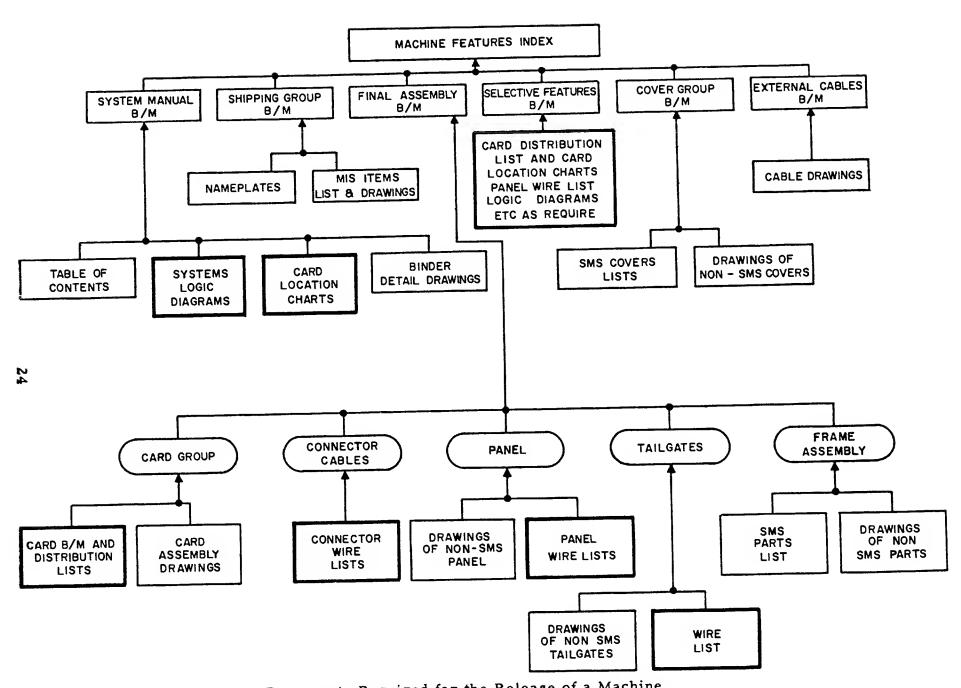

Tape Library where system logic pages and panel wire lists are retained on magnetic tape.

700 Series Program Release Office to control production programs.

Accounting Machine Section where miscellaneous card outputs from design automation programs are formalized.

To Release a Machine, the design groups furnish the Engineering Records Department with documents describing the machine. From these documents the Engineering Records group will compile the bills of material and the machines features index. The chart shows what these documents are, and in heavy lined squares which documents can at present be generated by design automation.

In addition, computer programs are used to maintain the bill of materials (Parts Usage Maintenance Programs or PUMP) and to maintain the table of content of system manuals (Change Control System Programs).

Documents Required for the Release of a Machine (Heavy-lined Blocks Indicate those Documents by Design Automation)
